

A TRUE'S BEAKED WHALE (*MESOPLODON MIRUS*) ON THE COAST OF BRAZIL: ADDING A NEW BEAKED WHALE SPECIES TO THE WESTERN TROPICAL ATLANTIC AND SOUTH AMERICA

SHIRLEY P. DE SOUZA¹, SALVATORE SICILIANO², SANDRA CUENCA³, BIANCA DE SANCTIS⁴

Abstract: A male True's Beaked Whale (*Mesoplodon mirus*) stranded alive on 04 May 2004, on the northern coast of São Paulo State, southeastern Brazil, and died twenty minutes later. To date, this species has only been recorded from the North Atlantic, southeast Africa and southern Australia. The complete skeleton was saved and the heart, stomach, testis, epizoites, samples of tissues, and blood were collected. This is the first record of *M. mirus* for the Western Tropical Atlantic (south of the Equator) and for South America. The record provides important information on this poorly known species.

Resumen: Un varamiento de un macho vivo de Zifio de True (*Mesoplodon mirus*) ha ocurrido en la costa norte de la Provincia de São Paulo, en el 4 de Mayo de 2004. El animal se ha muerto veinte minutos después de varado. Esta especie ha sido registrada solamente en el Atlántico Norte, sureste de África, y sur de Australia. El esqueleto completo ha sido colectado así como el corazón, estómago, testículos, epizoicos, muestras de tejidos y sangre. Este registro es el primer de *M. mirus* para el Atlántico Sur-Occidental y para la América del Sur, aportándonos importantes informaciones para esta especie poco conocida.

Keywords: *Mesoplodon mirus*, True's beaked whale, stranding, distribution

Introduction

Beaked whales of the genus *Mesoplodon* are the least known group among cetaceans. Their distribution, biology, behavior and external morphology are not fully described and the few data about them primarily come from analysis of skeletons and carcasses of stranded animals (Dalebout *et al.*, 1998). Only 11 published records of stranded *Mesoplodon* are known for Brazil: Four *M. grayi*, three *M. densirostris*, two *M. europaeus*, one *M. layardii*, one *M. cf. layardii* and one *M. hectori* (Siciliano, 1994; Secchi and Zarzur, 1999; Pinedo *et al.*, 2001; Zerbini and Secchi, 2001; Santos *et al.*, 2003; Martins *et al.*, 2004; Maia-Nogueira and Nunes, this issue).

True's beaked whale, *Mesoplodon mirus*, is among the least recorded species of *Mesoplodon*. The majority of records are in the Northwest Atlantic and less frequently in Ireland, France and Canary Islands, suggesting a probable relation with the Gulf Stream system (Mead, 1989; MacLeod, 2000). In the Southern Hemisphere they have been recorded in southeastern Africa and southern Australia. It is not clear whether populations of different hemispheres are geographically separated, or if the species distribution is wider than indicated by the known records (Ross, 1984).

Material and Methods

On 04 May 2004 a True's beaked whale stranded alive in São Sebastião (23°46'S - 45°40'W), northern coast of São Paulo state, southeastern Brazil (Figure 1). According to local people, the animal died after 20

minutes of unsuccessful attempts to return it to sea.

Soon after death, the animal was photographed and morphological measurements were taken following the procedures of Norris (1961) and Perrin (1975) (Table 1). Swabs from the various orifices were collected as well. Tissue samples of muscle, blubber, skin, heart, lung, liver, kidney, pancreas, spleen (including accessory spleens), bladder, prostate, testes and intestine were also taken for histopathological, microbiological and contaminants analysis. Stomach contents, external and internal parasites, feces, blood and the complete skeleton were also collected. The mandibles, in which there were no teeth or alveoli, were cleaned by maceration, with care being taken to avoid the loss of any fragment which could aid in species identification. The skull and skeleton were recovered after three weeks and 10 months, respectively. The complete skeleton has been deposited at *Instituto Terra & Mar* under catalogue number SOSMM 130. The skull and mandibles were measured with calipers to the nearest 0.1mm following procedures of Moore (1963) and Ross (1984).

Results and Discussion

The specimen was identified as a True's beaked whale (*Mesoplodon mirus*) based on the presence of the following characteristics: Tooth crypts (*i.e.* internal chambers corresponding to future alveoli) positioned in the tip of both hemi-mandibles (observed by X-ray, Figure 2), skull and mandible morphology (Figures 3 and 4), and diagnostic external coloration described for the species in the Southern Hemisphere (Baker, 1983).

MORPHOLOGICAL MEASUREMENTS DESCRIPTION	cm
1. Length, total (tip of upper jaw to deepest part of notch between flukes)	460
2. Length, tip of upper jaw to center of eye	58
3. Length, tip of upper jaw to apex of melon (snout length)	14
4. Length of gape (tip of upper jaw to angle of gape)	37
5. Length, tip of upper jaw to external auditory meatus	68
6. Center of eye to external auditory meatus (direct)	12
7. Center of eye to angle of gape (direct)	20
8. Center of eye to center of blowhole (direct)	20
9. Length, tip of upper jaw to blowhole along midline	55
10. Length, tip of upper jaw to anterior insertion of flipper	93
11. Length, tip of upper jaw to tip of dorsal fin	306
12. Length, tip of upper jaw to midpoint of umbilicus	204
13. Length, tip of upper jaw to midpoint of genital aperture	297
14. Length, tip of upper jaw to center of anus	328
15. Girth, on a transverse plane intersecting axilla	212
16. Girth, on a transverse plane intersecting the anus	150
17. Length, flipper (anterior insertion to tip)	45
18. Length, flipper (axilla to tip)	41
19. Width, flipper (maximum)	15
20. Height, dorsal fin (fin tip to base)	17
21. Width, flukes (tip to tip)	117
22. Distance from nearest point on anterior border of flukes to notch	36

Figure 2. Position of the teeth's crypts

Figure 3. Skull of the *M. mirus* specimen

Figure 4. Mandibles of the *M. mirus* specimen

The individual was a 460cm long male, with gray coloration on its anterior dorsal body, and a white area from the anterior insertion of the dorsal fin to the insertion of the flukes, as previously described for Southern Hemisphere specimens by Mead (1989). There was a dark circular area around each eye and a light gray ventral area from the chin to the line between the flippers (see Figure 1). A white elliptical patch connecting the anal and genital slit was also present. Below each flipper there was an area of lighter pigmentation corresponding exactly to the flipper's contour. We noted that in this particular specimen, the conspicuous coloration of the fresh carcass agreed with the known coloration for the Southern Hemisphere specimens of *M. mirus* (Figure 1).

The dorsal fin was small, with a slightly concave posterior border and situated on the posterior third of the body. There was no central fluke notch. Several wounds and scars were present on the flanks and dorsal region, very similar to those caused by the cookie-cutter shark, *Isistius* sp. (Figure 5).

The condylobasal length of the skull was 75cm and the vertebral formula was $C7 + T10 + L11 + Ca 20 = 48$, which fits within the range for *Mesoplodon* cited by Mead (1989): $C7 + T 9-11 + L 8-11 + Ca 17-21$. Cranial measurements were taken following Moore (1963) and Ross (1984) and are shown in Tables 2 and 3.

The skull showed a very developed vertex (Figure 3) and the mesorostral channel was ossified. After maceration the mandible revealed an opened symphysis and an absence of teeth or alveoli (Figure 4). By

examining the mandible through X-ray plates it was possible to determine "crypts of the teeth" in the tip of both hemi-mandibles. A total of 10 pairs of ribs, 4 sternbrae, 2 scapulas, 2 humerus, 2 radius, 2 ulnas, 24 bones from both manus, the complete hyoid apparatus and 11 chevrons were recovered. All the vertebra epiphyses were fused to their centra, as were all the epiphyses from the forelimb bones, the ventral hyoids and 9 of the 11 chevrons. This indicates that this male was physically mature. The last four right ribs presented marks of calcified fractures. The lack of any alveoli or teeth suggests that this was an anomalous specimen. Despite its physical and close-to sexual maturity, teeth did not develop during the course of its life, which is unusual for a male mesoplodont (Mead, 1989).

The main (fundic) stomach was 38cm long in its greatest length and 15cm wide in its greatest width, and the pyloric stomach was composed of four smaller interconnected sac-like structures. The stomach contained no food items, but pieces of plastic were present (Figure 6). There was a slight infection ($n=5$) of *Anisakis* sp. parasites in the last chamber of the stomach. These parasites could not be classified to the species level due to the fact that all specimens were female (Dr. Luís C. Muniz-Pereira⁵, pers. commn, 2005). Previously, plastic debris has been found in other stranded beaked whales (e.g. in three beaked whales stomachs in the North Atlantic - Santos *et al.*, 2001, and in a *M. densirostris* specimen from southern Brazil - Secchi and Zarzur, 1999), indicating a potential problem with marine debris on this particular group of whales.

16. Length of nasal suture	6.1	8.1
17. Breadth of skull across postorbital process of frontals	37.8	50.4
18. Breadth of skull across zygomatic processes of squamosals	36.4	48.5
19. Breadth of skull across centres of orbits	35.3	47.1
20. Least breadth of skull across posterior margins of temporal fossae	20.4	27.2
21. Greatest span of occipital condyles	10.9	14.5
22. Greatest width of an occipital condyle	4.0	5.3
23. Greatest length of an occipital condyle	8.1	10.8
24. Greatest breadth of foramen magnum	3.8	5.1
25. Breadth of skull across exoccipitals	30.2	40.3
26. Breadth of nasals on vertex	3.9	5.2
27. Least distance between premaxillary crests	1.8	2.4
28. Greatest span of premaxillary crests	15.7	20.9
29. Least width of premaxillae where they narrow opposite superior nares	3.7	4.9
30. Greatest width of premaxillae anterior to place of measurement # 29	L= 5.2 R= 6.1	6.9 8.1
31. Width of premaxillae at midlength of rostrum	1.8	2.4
32. Width of rostrum in apices of antorbital notches	17.1	22.8
33. Greatest width of rostrum at midlength of rostrum	7.4	9.8
34. Greatest depth of rostrum at midlength of rostrum	4.9	6.5
35. Greatest transverse width of superior nares	5.0	6.7
36. Greatest inside width of inferior nares on the pterygoids	10.4	13.9
37. Height of skull	26.9	35.9
38. Greatest width of temporal fossa	8.2	10.9
39. Least distance between maxillary foramina	8.5	11.3
40. Least distance between premaxillary foramina	4.3	5.7
41. Distance from posterior margin of left maxillary foramen to most anterior extension of left maxillary prominence	6.6	8.8
42. Greatest length of vomer visible at surface of palate	13.6	18.1
43. Length of tympanic bulla, left	4.2	5.6
44. Length of tympanic bulla, right	4.4	5.8

Table 3. Mandibular measurements of a *Mesoplodon mirus* specimen, stranded in São Sebastião, São Paulo, Brazil in May 2004.

MANDIBULAR MEASUREMENTS DESCRIPTION		cm	% CBL
1.	Length of mandible	63.1	84.1
2.	Greatest length of symphysis	13.5	18
3.	Height of mandible at coronoid process	11.3	15.1
4.	Outer height of mandible at midlength of alveolus	---	---
5.	Inner height of mandible at midlength of alveolus	---	---
6.	Length from most posterior extension of symphysis to most posterior of condyle	48.9	65.2
7.	Length from posteriormargin of alveolus to condyle	---	---
8.	Length of alveolus	---	---
9.	Width of alveolus	---	---

**Figure 6.** Plastic debris found in the *M. mirus* stomach

The only organ which could be measured and weighed was the left testis, measuring 23cm in length and weighing 124.9g. Considering the turgid aspect of the testes, the physical maturity of the skeleton, and the whale's total length - very close to the maximum length for the species- this specimen could be close to or fully sexually mature. According to Mead (1989) the mean weight of the gonads of sexually mature males of *Mesoplodon* is 140-250g. These values are close to that obtained for the current specimen's testis.

Externally, the heart was 40cm wide and 32cm in height, and showed features similar to those found in other mammal hearts: four cavities (two atria and two ventricles). Detailed analysis of its anatomy is being carried out to describe its internal features.

Despite the blood sample becoming hemolyzed,

analysis revealed a high level of hemoglobin (30.3g/dL), which could be a characteristic of deep-diving species. Two other species with characteristic offshore distribution, *Delphinus delphis* and *Lagenorhynchus obliquidens*, show lower hemoglobin values of 16.1-19.4 and 17-20g/dL, respectively (Bossart *et al.*, 2001). High values of leukocytes (94,200 cells/mm³) were also found and the presence of numerous bacteria (cocci) could suggest septicemia. Cultures of the swabs collected from the mouth, blowhole, *Isistius* bites, anal and genital splits, confirmed the presence of *Vibrio vulnificus*, *V. parahemolyticus*, *V. alginolyticus*, *V. fluvialis*, *Vibrio* sp., *Aeromonas sobria* and *A. veronii*. Swab cultures from this specimen were negative for *Salmonella*. Other studies on stranded cetaceans in Brazil have shown the presence of *Vibrio vulnificus* and *V. fluvialis* in *Sotalia fluviatilis*, *Aeromonas veronii* and *Vibrio fluvialis* in

⁶ Dr. Dália dos Prazeres Rodrigues, /Laboratório de Enterobactérias/IOC/FIOCRUZ, Rua Leopoldo Bulhões, 1480-térreo, Manguinhos, Rio de Janeiro, RJ, 21041-210, Brazil.

Eubalaena australis and *Vibrio alginolyticus* and *Aeromonas sobria* in *Pontoporia blainvillei* (S.Siciliano and D.P.Rodrigues, unpublished data, 2005).

A few epizootes identified as *Penella balaenoptera* were found fixed to the whale's left flank, confirming *M. mirus* as a host for this copepod (Mead, 1989).

The record of this specimen provides important information about external morphology, osteology, anatomy and natural history for this relatively poorly known species. Additionally, it confirms the presence of *M. mirus* in the Western Atlantic south of the Equator, just midway among other confirmed stranding areas: North Atlantic, southeastern Africa and southern Australia. Until now, the presence of *M. mirus* in the Southern Hemisphere had been confirmed only for warm-temperate waters of the Indian and South Pacific Oceans (Mead, 1989). MacLeod (2000) mentioned that these few occurrences could be from a population separated from that of the Northern Hemisphere, suggesting an anti-tropical distribution for this species. The coloration of this individual from Brazil (SOSMM 130) is consistent with such an anti-tropical distribution, being more similar to other Southern Hemisphere individuals than to ones from the North Atlantic, despite the closer proximity between southern Brazil and the southern-most tip of the range of *M. mirus* in the Northwestern Atlantic (MacLeod, 2000). Therefore, this specimen suggests that in the Southern Hemisphere, *M. mirus* probably has a wider distribution than previously thought, but that animals in the North Atlantic and Southern Hemisphere form different breeding populations even within the Atlantic, with different distinct colorations. The present record adds a new beaked whale species for the western South Atlantic as well as for South America and increases to 44 the number of cetaceans recorded for the Brazilian coast.

Acknowledgements

We thank Projeto SOS Mamíferos Marinhos team for helping during necropsy, particularly Fernanda de N. Caso, Márcio T. Silva, Monique Winck and Rafael N. Abib. MSc. Juliana Marigo and Daphne Wrobel provided useful literature and Manoel Trindade for taking the photo shown in this article. Dr. Sheila M. F. Mendonça de Souza (FIOCRUZ/ENSP/Departamento de Endemias, Laboratório de Paleopatologia) kindly examined x-rays from the mandible and commented on the tooth positions. Dr. Luís C. Muniz-Pereira (Instituto Oswaldo Cruz/FIOCRUZ, Departamento de Helminologia) identified the parasites found in the stomach, Dr. Tagea K. S. Björnberg (CEBIMar - USP) identified the epizootes. Dr. Dália dos Prazeres Rodrigues and Dr. Marise D. Asensi (Instituto Oswaldo Cruz/FIOCRUZ, Departamento de Bacteriologia, Laboratório de Enterobactérias) analyzed the collected swabs. Dr. Colin MacLeod confirmed the species identification and, together with Dr. Alan Baker, one

anonymous referee and the editors, provided useful comments to the manuscript.
